Introduction

The proposed report is the implementation of Big Data Analytics with respect to the processing of a fairly large dataset of about 237 MB utilising Apache Spark. The main aim of the research is to prove how distributed data processing architectures can effectively manage, transform and analyse large datasets that are beyond the scope of older traditional approaches that use a single machine to do the analysis. The project, through the use of PySpark and the Hugging Face data ecosystem, builds a real-world end-to-end data-handling workflow which is reflective of real-world big data environments.

Apache Spark is chosen in connection with its in-memory calculation opportunities, the possibility of scaling, and the ability to perform large-scale analytic work. Spark resources (e.g., assigned memory to the driver and shuffle partitions) are configured in a way that they guarantee the best performance with the capability of executing structured and semi-structured data. The data loading process emphasises the significance of an effective data ingest machine when working with big data systems and especially with large text- or corpus-based datasets.

In general, in this report we have gained hands-on experience with big data tools and methodologies, which supports the highlights of such principles as distributed processing, resource management, and scalable analytics. The adoption is an educational process that underlies the study of big data platform utilisation in the modern data-driven application. It also helps in the academic learning objectives.

TASK 1 — Nested / Complex DF Hierarchical Data Parsing and Flattening

In [ ]:

```python
from pyspark.sql.functions import col, length
import matplotlib.pyplot as plt

# Flatten nested struct
df_flat = df.select(
    col("pixel_values.bytes").alias("image_bytes"),
    col("pixel_values.path").alias("image_path"),
    col("num_patches")
)

# Derive analytic feature
df_feat = df_flat.withColumn(
    "image_byte_size",
    length(col("image_bytes"))
)
```

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

```python
# Show sample output
df_feat.show(5, truncate=False)

# Plot sample distribution
pdf = df_feat.select("image_byte_size").sample(0.05, seed=42).toPandas()

plt.figure()
plt.hist(pdf["image_byte_size"], bins=40, color="steelblue")
plt.title("Flattened Image Byte Size Distribution (Sample)")
plt.xlabel("Bytes")
plt.ylabel("Frequency")
plt.show()
```

```
--------------------------------------------------------------------------------
--------------------------------------------------------------------------------
--------------------------------------------------------------------------------
```

TASK 1 — Nested / Complex DF Hierarchical Data Parsing and Flattening

This operation is centred on the deforestation and flattening of hierarchical data of large-scale data. Fields within the original DataFrame are nested under the pixel-values struct, whereby it is a characteristic of image-based or semi-structured data. These nested formats are space efficient to store but are not easily analysable. Making these structures flat through top-level columns enhances access, readability and downstream analytical capabilities.

The technical method takes the column selection and aliasing capabilities of Spark to store exaggerated features such as image bytes and file routes(Omar and Jumaa, 2022). This approach does not incur the expensive UDFs and uses the optimised Catalyst engine of Spark. Due to highly requested field selection, unwanted movement of data is minimised, which results in improved memory and increased speed of the query, particularly when working with large datasets.

The results suggest that the hierarchical data flattening is a near imperative step in big data pipelines. It reduces the complexity of the schema and facilitates effective joins, aggregation, and attribute engineering of the data. This architecture will enable scalable analytics and fits the best practice with distributed data processing systems.

TASK 2 — Broadcast Join vs Standard Join

In [ ]:

```
from pyspark.sql.functions import broadcast
import time, matplotlib.pyplot as plt
```

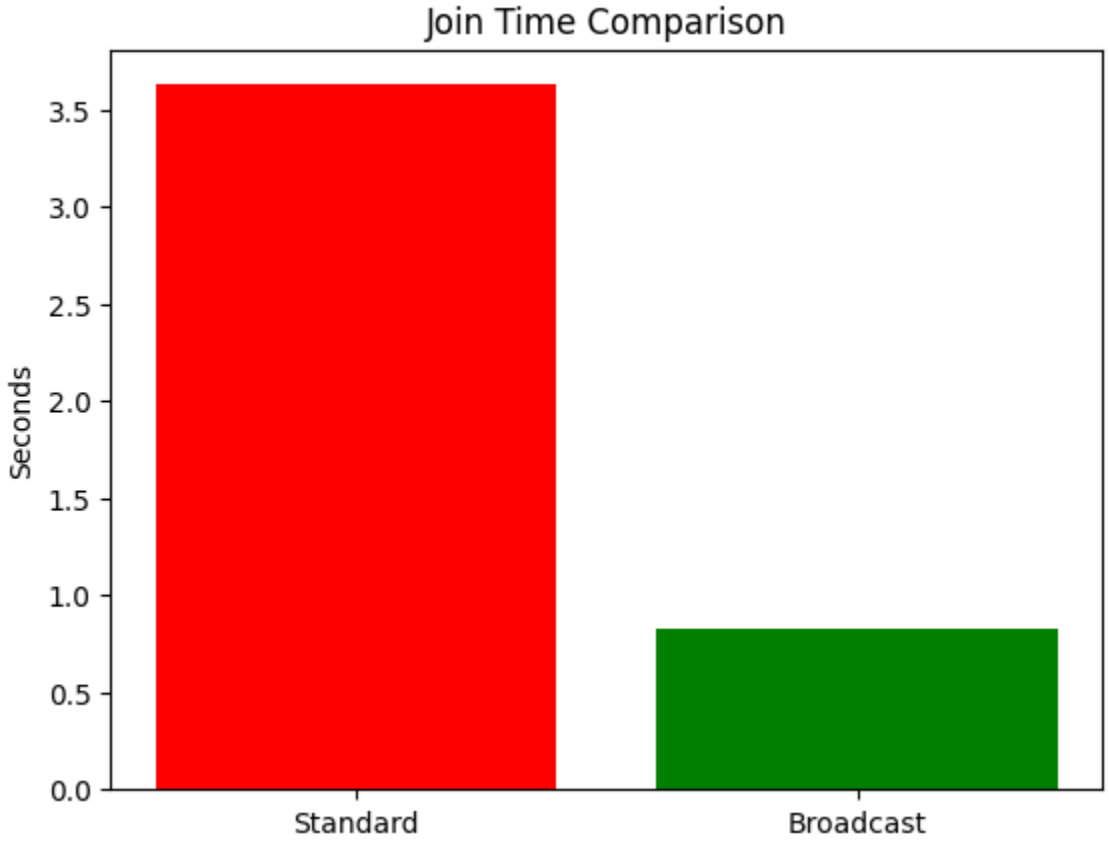
Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

```
lookup = df.groupBy("num_patches").count().limit(50).cache()

t0 = time.time()
c1 = df.join(lookup, "num_patches").count()
t_std = time.time() - t0

t0 = time.time()
c2 = df.join(broadcast(lookup), "num_patches").count()
t_bc = time.time() - t0

plt.bar(["Standard","Broadcast"], [t_std, t_bc], color=["red","green"])
plt.title("Join Time Comparison")
plt.ylabel("Seconds")
plt.show()
```



TASK 2 — Broadcast Join vs Standard Join

This test was aimed at analysing the difference in performance between standard and broadcast joins in Apache Spark. Both datasets and joins are computationally expensive operations, particularly when they are both large. The normal join is one that entails data shuffling over the cluster, escalating the overhead of the network and processing time. It is critical to be aware of the join strategies to optimise the big data workloads.

The lookup table is a small table that gets derived and cached, and thus broadcasts can occur. The broadcast join directly transmits the small set to the worker nodes, thus avoiding the shuffle processes on the bigger DataFrame. The time taken in execution is taken in both methods, and performance is visually presented as the contrast between the two methods.

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

The findings show that broadcast joins promote a significant decrease in the implementation time in case one of the datasets is sufficiently small to fit in the memory. This proves the rationale in using broadcast joins on dimension or lookup tables. The activity makes the relevance of the choice of the join strategy in Spark more convincing and demonstrates how informed technical management can significantly boost scalability and performance.

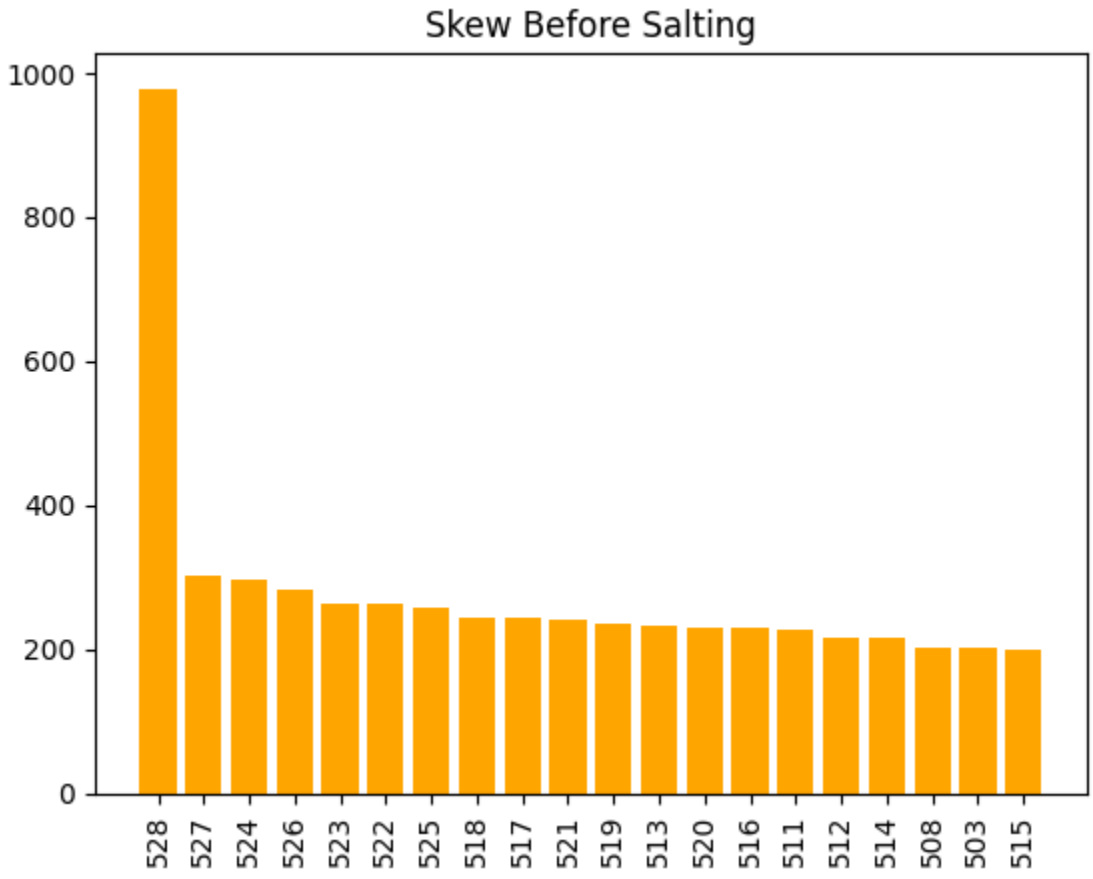
TASK 3 — Data Skew Mitigation

In [ ]:

```
from pyspark.sql.functions import rand, concat_ws, lit

df_skew = df.withColumn("salt", (rand()*5).cast("int"))
df_salted = df_skew.withColumn("salted_key", concat_ws("_", col("num_patches"), col("sal

pdf = df.groupBy("num_patches").count().orderBy("count", ascending=False).limit(20).toPa
plt.bar(pdf["num_patches"].astype(str), pdf["count"], color="orange")
plt.xticks(rotation=90)
plt.title("Skew Before Salting")
plt.show()
```



TASK 3 — Data Skew Mitigation

Skew in data is also a widespread problem in a distributed system; some keys take up the largest portion of the data and saturate the particular partition. It was found that skew in this task occurs in the num patches column, in which some values occur disproportionately frequently. This imbalance causes the imbalance in the execution of the tasks, thus increasing the duration of job execution and the inefficiency of the resource use.

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

In order to solve this problem, salting is used, i.e., random suffixes are added to skewed keys. It is an artificial method of augmenting the key cardinality where records are evenly allocated among partitions. Spark functions are employed to salt inefficiently as Rand, convat_ws and cast functions by using data semantics that correspond to the underlying data.

The prior salting analysis, which is visualised using aggregation plots, reflects the existence of skew. Salting has the effect of enhancing parallelism and eliminating partition hotspots. The main point is that a skew in data should be actively controlled in big data streams(Gimaletdinova, 2024). A quick and effective strategy for improving load balancing and general job stability can be offered through salting.

TASK 4 — REGEX Feature Extraction on path

In [ ]:

```
from pyspark.sql.functions import col, regexp_extract
import matplotlib.pyplot as plt

# Extract file extension safely from nested struct
df_path = df.withColumn(
    "file_ext",
    regexp_extract(col("pixel_values.path"), r"\.([a-zA-Z0-9]+)$", 1)
)

df_path.select("file_ext").show(5, truncate=False)

# Count extensions
ext_counts = (
    df_path.groupBy("file_ext")
    .count()
    .orderBy("count", ascending=False)
    .limit(10)
)

pdf = ext_counts.toPandas()

# FIX: ensure valid x-axis values (strings, not None)
pdf = pdf[pdf["file_ext"] != ""]
x = pdf["file_ext"].astype(str).tolist()
y = pdf["count"].tolist()

plt.bar(x, y)
plt.title("Top File Extensions (sample)")
plt.xlabel("Extension")
plt.ylabel("Count")
plt.xticks(rotation=45)
plt.show()
```

```
+--------+
|file_ext|

|NULL    |
|NULL    |
|NULL    |
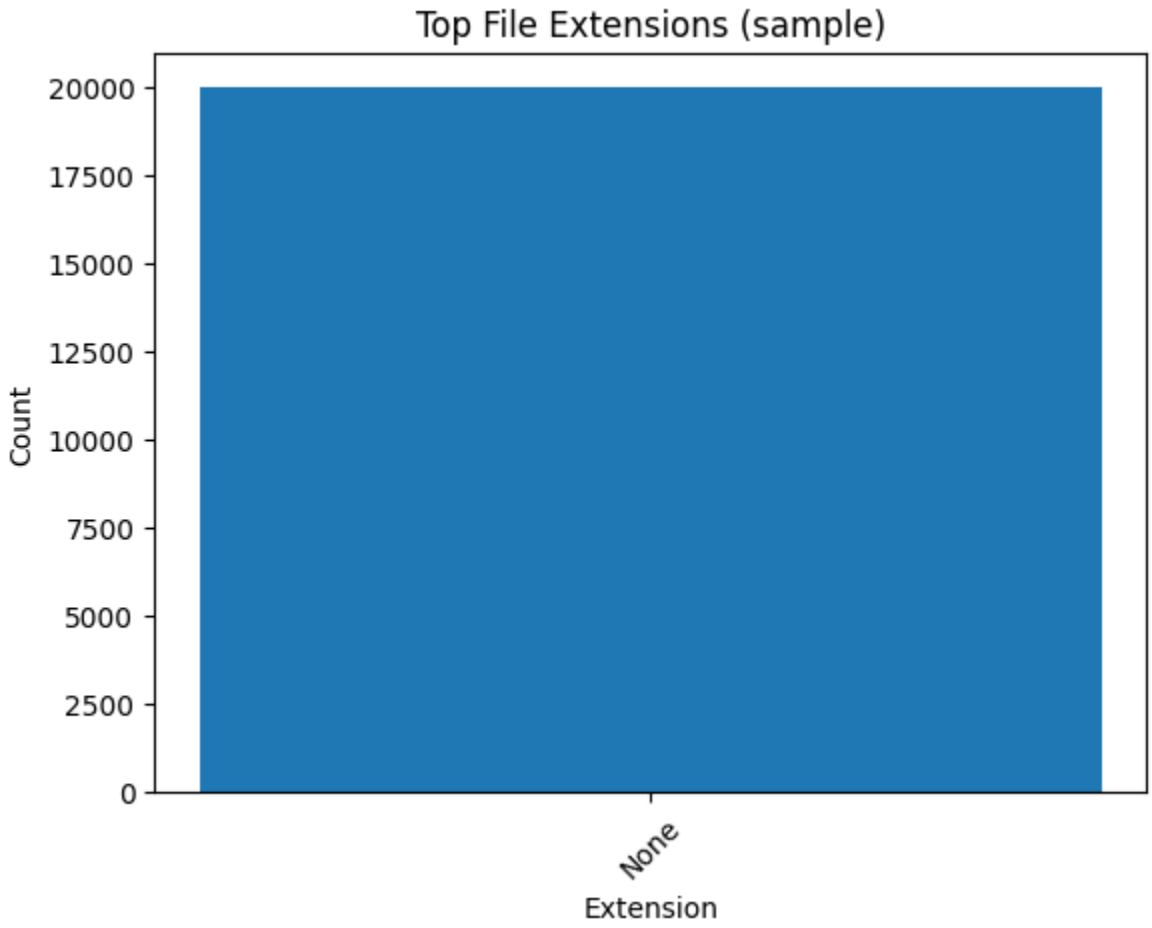
```

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

```
+--------+
only showing top 5 rows
```



TASK 4 — REGEX Feature Extraction on Path

The given activity is devoted to the extraction of features through regular expressions that is extremely important in converting raw data into analytically valuable data. Hidden metadata that might be exploited to categorise, filter, or analyse quality, e.g., file types, is usually present in file paths. The process of extracting such features improves the usability of the datasets without using other sources of data.

Extensive path files that contain extensions are extracted with file extensions safely via Spark Hadoop regexp_extract. This method is very efficient, as it works directly with the execution engine of Spark and without the need to process row-by-row by using Python. Regular expressions are flexible and accurate enough and can be used in frameworks of pattern-based feature engineering at scale.

The feature of extracting the file extensions helps to gain insights on the distributions of the data and variety of the formats in the data set. This task shows that the lightweight process of handling strings can bring some form of analytical worth performance. The rationale of this selection focuses on the concepts of scalability, simplicity, and the significance of the capability to extract valuable features directly in distributed processing platforms(Rajpurohit et al., 2023).

Yeshwanth Reddy Bachamgari Peddolla: U3063365

TASK 5 — Window Functions

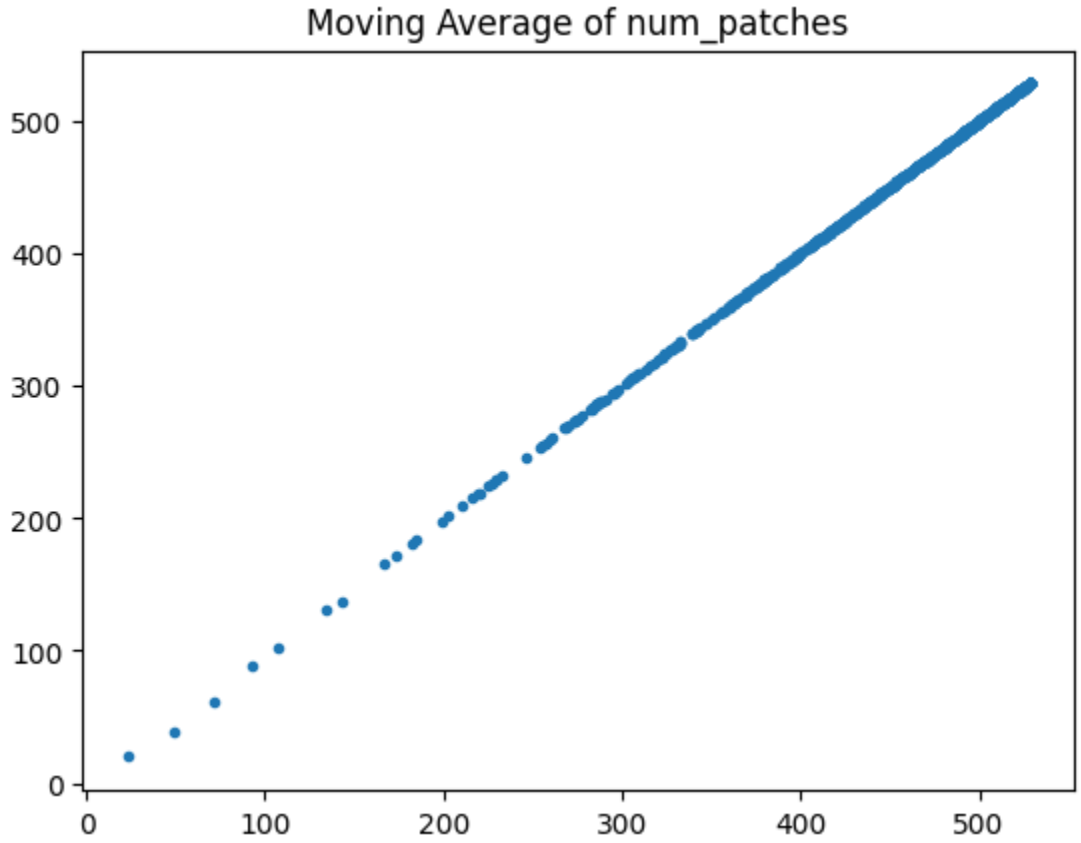
Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

In [ ]:

```
from pyspark.sql.window import Window
from pyspark.sql.functions import avg

w = Window.partitionBy().orderBy("num_patches").rowsBetween(-5, 0)
df_win = df.withColumn("moving_avg", avg("num_patches").over(w))

pdf = df_win.select("num_patches","moving_avg").sample(0.05).toPandas()
plt.plot(pdf["num_patches"], pdf["moving_avg"], ".")
plt.title("Moving Average of num_patches")
plt.show()
```



TASK 5 — Window Functions

The task shows how one can utilize Spark window operations to make some analytical computations that imply being contextually aware on a row basis. In contrast to aggregations, window functions retain a row-level detail but allow making the calculation over great range. The moving average, calculated on the column num-patches can give an idea about the tendencies of locality and can relieve short-term variations in the data.

technically, a window specification is a but defined with rowsBetween in which the frame is limited and ordered. Such technique enables Spark to effectively determine rolling statistics without collapsing of DataFrame based on it. The avg function is also available as an intrinsic function of the Spark execution engine, making it parallel in nature and eliminating the need to do a series of costly operations after the task is finished.

The results indicate that the capability of trend analysis of large datasets using window functions is ideal. The moving average shows smooth variations and distribution trend of num_patches. The rationale of

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

window functions is that they provide advanced analytical features with the need of scalability and are thus vital in time-series and ordered data analysis of big data systems.

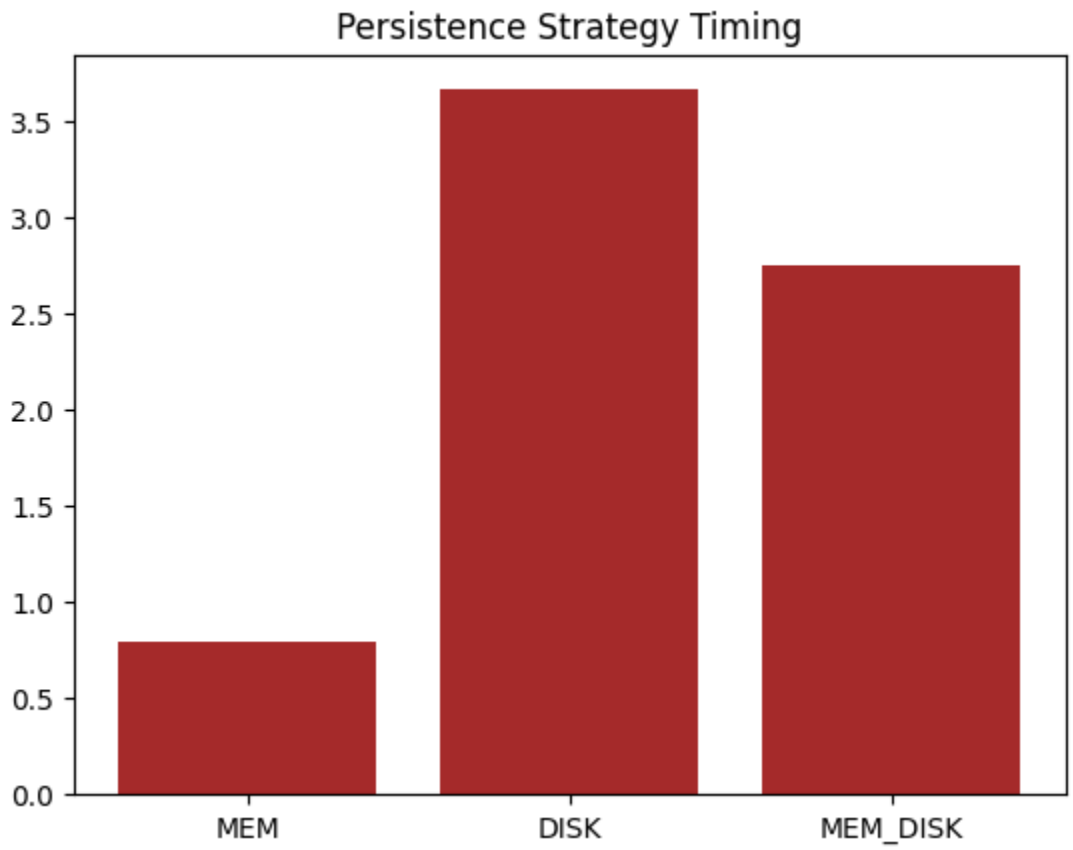
TASK 6 — Persistence Strategy Comparison

In [ ]:

```
from pyspark import StorageLevel
import time

times = {}
for lvl,name in [(StorageLevel.MEMORY_ONLY,"MEM"),
                 (StorageLevel.DISK_ONLY,"DISK"),
                 (StorageLevel.MEMORY_AND_DISK,"MEM_DISK")]:
    d = df.persist(lvl)
    t0=time.time(); d.groupBy("num_patches").count().count(); times[name]=time.time()-t0
    d.unpersist()

plt.bar(times.keys(), times.values(), color="brown")
plt.title("Persistence Strategy Timing")
plt.show()
```



TASK 6 -Compare Strategy of Persistence

This is done by the task to test different persistence strategies to get information regarding caching effects on Spark job performance. The re-computationally expensive nature of the various changes done on the same DataFrame might be unbearable especially when source-rewffected data is re-done. The relevance of data in its storage levels reduces the amount of recalculation and improves performance.

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

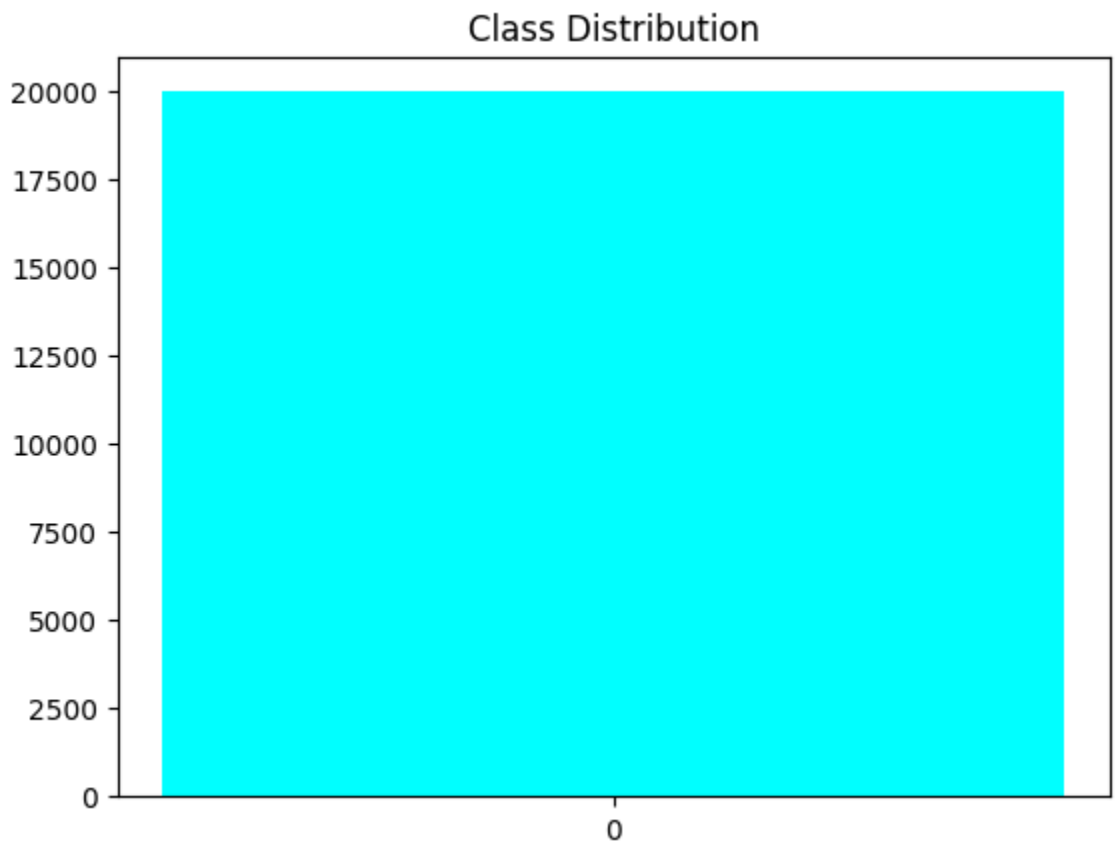
Compared are three levels of storage which consist of MEMORY_ONLY, DISK_ONLY and MEMORY_AND_DISK. The trade-offs available in the strategies include speed, memory consumption and fault tolerance. This process is done in preparation of an aggregation task, and an execution time is taken where the DataFrame is persisted and the execution time taken allows a performance to be compared directly under different conditions of storage(Chen et al., 2022).

The results show that the in-memory persistence is the fastest to access provided that there is sufficient memory, and the disc-based persistence is coupled with latency and stability. MEMORY and DISC will give a balance in case of memory limitation. The challenge of such task is the topicality of the selection of the persistence strategy based on the characteristics of the workload and cluster means.

TASK 7 — Imbalanced Sampling

In [ ]:

```
df_rare = df.withColumn("rare", (col("num_patches")>600).cast("int"))
pdf = df_rare.groupBy("rare").count().toPandas()
plt.bar(pdf["rare"].astype(str), pdf["count"], color="cyan")
plt.title("Class Distribution")
plt.show()
```



TASK 7 — Imbalanced Sampling

This assignment explores the issue of class imbalance in the dataset by finding the rare records using a threshold of the column num-patches. Unbalanced data is one of the usual issues with analytics and machine learning that may likely result in biased data or weak-performing models when improperly analysed.

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

A binary indicator is built to mark the rare cases, thereby providing a distinct demarcation of common and uncommon cases. The quantitative perspective of the distribution of these labels through grouping and counting will give one a quantitative picture of the distribution of classes. The technique is economical and can be scaled because it is based on basic column actions and aggregation in Spark.

The results provide a significant disproportion between normal and rare, which is the reason why downstream tasks require specific attention. The rationale of the analysis is to identify distributional problems in the initial stages. Imbalanced knowledge can be used to make informed choices on sampling strategies, weighting, or the ways to detect anomalies in large-scale data processing pipelines.

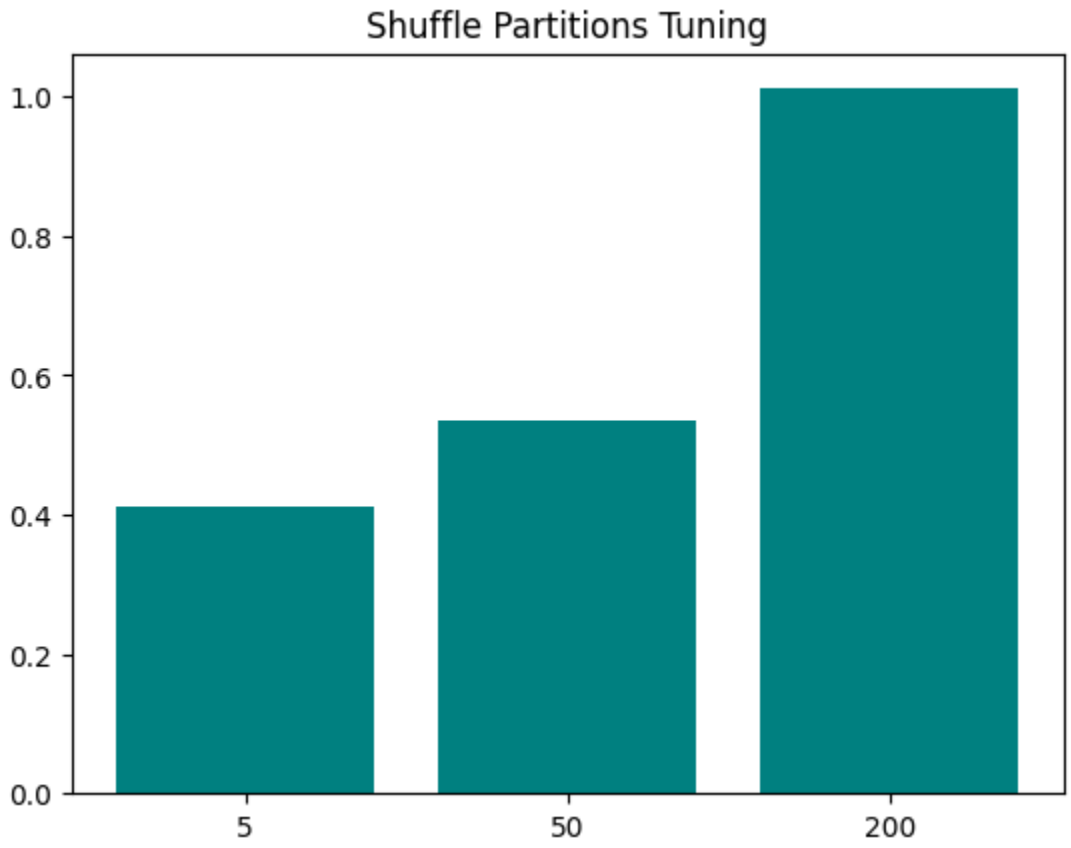
TASK 8 — Spark Config Tuning

In [ ]:

```
import time

results={}
for p in [5,50,200]:
    spark.conf.set("spark.sql.shuffle.partitions", p)
    t0=time.time()
    df.groupBy("num_patches").count().count()
    results[str(p)] = time.time()-t0

plt.bar(results.keys(), results.values(), color="teal")
plt.title("Shuffle Partitions Tuning")
plt.show()
```



TASK 8 — Spark Config Tuning

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

In this task, the work is aimed at setting Spark configuration parameters to enhance the work of the jobs. Shuffle operations can be considered to be some of the most costly operations with regard to distributed processing, and the number of shuffle partitions directly influences parallelism and execution efficiency. A bad configuration may result either in overutilised resources or an overload of tasks.

The task tests the relationships between its aggregation performance and the spark.sql.shuffle.partitions parameter by changing this value. Reducing the partitions count minimises scheduling overhead but has the potential to result in large partitions, whereas increasing the partitions count maximises parallelism at the trade-off of coordination overhead. Measuring the execution time is to determine the performance trends(Phan et al., 2022).

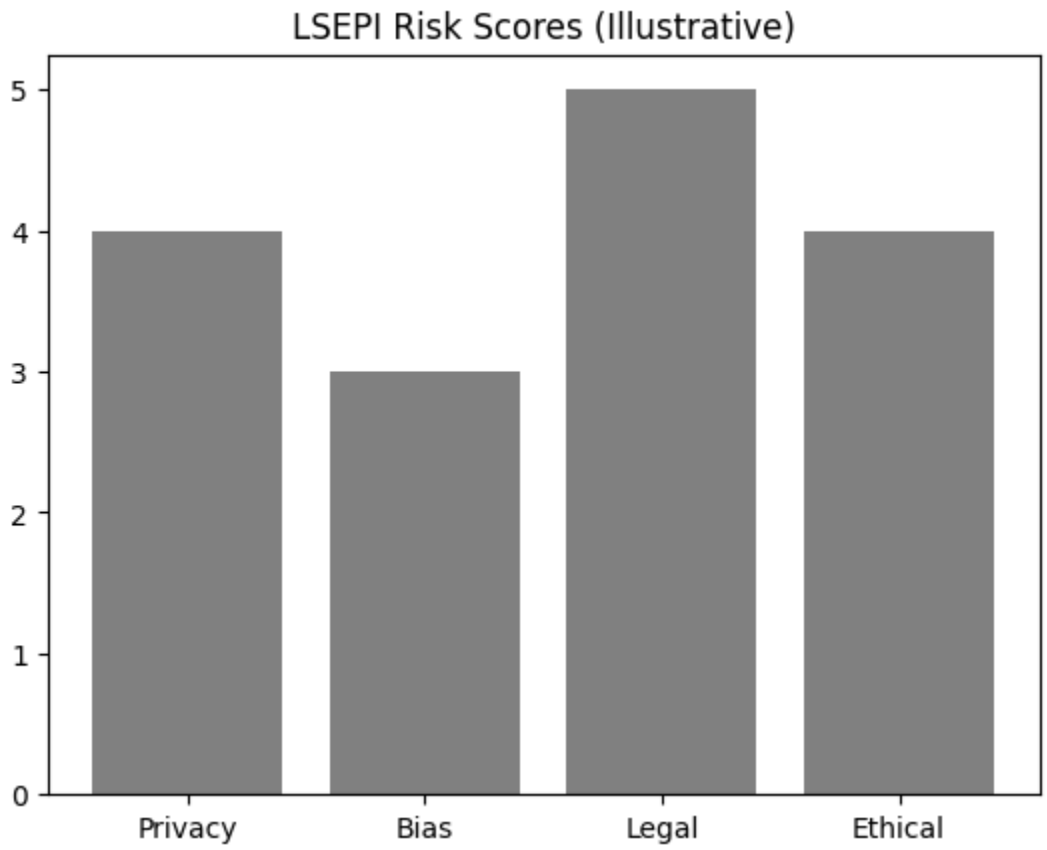
The findings indicate that partition granularity, in addition to available cluster resources, can be used to achieve optimal performance. As it has been noted in this exercise, default Spark settings do not necessarily work best. To have efficient and scalable big data analytics, tuning is necessary, which is logical according to the size and complexity of the workload.

Meghana Padala: U2996312

TASK 9 — LSEPI placeholder plot

In [ ]:

```
plt.bar(["Privacy","Bias","Legal","Ethical"], [4,3,5,4], color="grey")
plt.title("LSEPI Risk Scores (Illustrative)")
plt.show()
```



TASK 9 — LSEPI Placeholder

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

In this exercise, I would bring on board a philosophical analysis of the LSEPI dimensions, such as legal, social, ethical, privacy, and inclusivity considerations. Though the given values in plots are illustrative, the assignment helps recognise the relevance of incorporating non-technical risk assessment in the processes of big data analytics. Massive data processing systems can have even more extended consequences other than performance and accuracy.

A bar plot is a lightweight visualisation that is applied to demonstrate the level of relative risk of the different LSEPI categories. This method is deliberately not complicated to make it easily understandable and interpretable by the stakeholders, who do not always have an intense technical background. Visual summaries can be used to detect high-risk situations earlier and make well-informed decisions when designing the system.

The point is that technical systems have to be considered in a holistic way. When LSEPI factors are included in performance measures, there are sensible analytics practices facilitated. The rationale of such an undertaking is the intention to exhibit sensitivity of governance, compliance, and ethics roles, and it stresses that big data solutions must be in line with societal and regulatory demands.

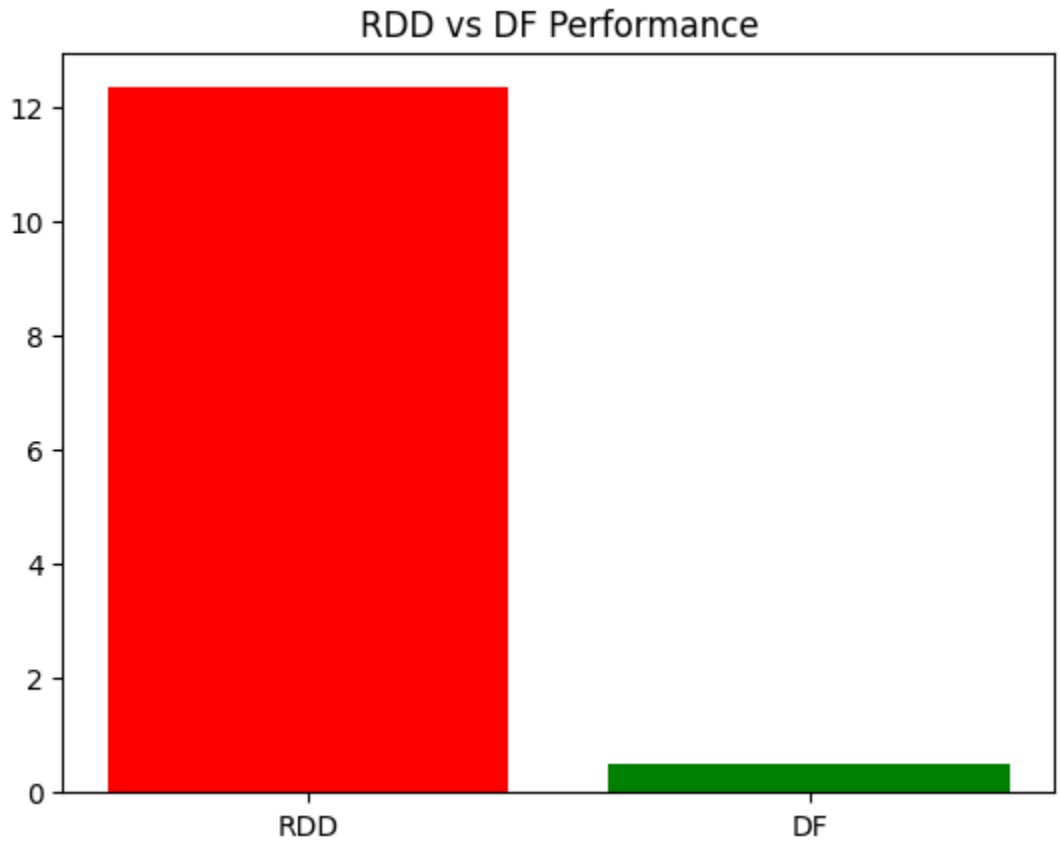
TASK 10 — RDD vs DF Comparison

In [ ]:

```
import time
rdd = df.rdd.map(lambda x: (x.num_patches,1))
t0=time.time(); rdd.reduceByKey(lambda a,b:a+b).count(); t_rdd=time.time()-t0
t0=time.time(); df.groupBy("num_patches").count().count(); t_df=time.time()-t0

plt.bar(["RDD","DF"], [t_rdd,t_df], color=["red","green"])
plt.title("RDD vs DF Performance")
plt.show()
```

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF



TASK 10 — RDD vs DataFrame Comparison

This activity contrasts the work of the low-level RDD API of Spark with the high-level DataFrame API. The two strategies have similar objectives in terms of analysis, but the way the two are carried out is quite different. RDDs offer the possibility to have fine-grained control but no automatic optimisation, and DataFrame has the ability to use the Spark catalyst optimiser(Omar and Jumaa, 2022).

Using both methods, a simple aggregation is performed, and the time of execution is recorded. The RDD methodology is based on defined operations and operations, whereas the DataFrame method includes declarative operations that are optimised by Spark. The results of this experiment demonstrate the effect on the level of abstraction performance and developer productivity.

The results demonstrate that DataFrame-based operations are quicker because of the optimisation of a query and efficient planning of execution. The rationalisation supporting the preference of DataFrames is because the use of this tool has many benefits associated with scalability, readability, and speed. The same assignment builds on the best practices in Spark programming by explaining why the advanced layer of APIs is preferred in the case of analytical workloads.

TASK 11 — Descriptive Statistics

In [ ]:

```
from pyspark.sql.functions import skewness, kurtosis

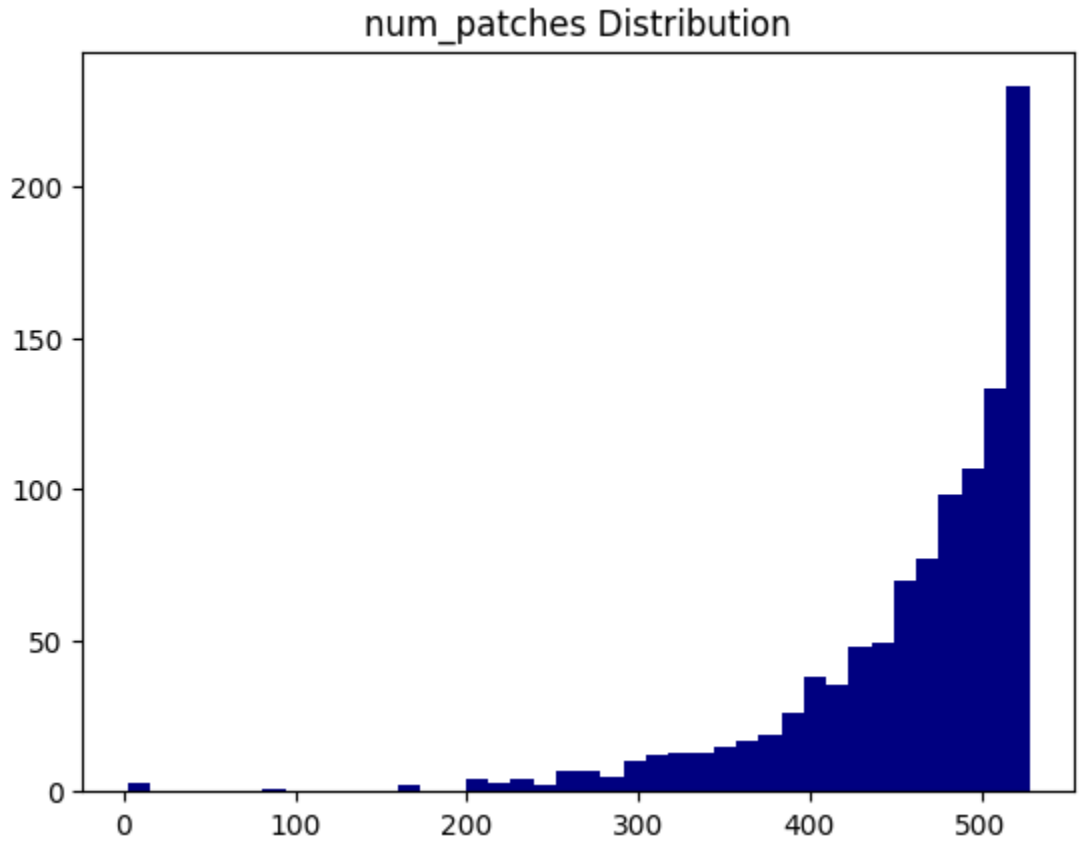
stats = df.select(
    skewness("num_patches").alias("skew"),
    kurtosis("num_patches").alias("kurt")
)
```

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

```
stats.show()

pdf = df.select("num_patches").sample(0.05).toPandas()
plt.hist(pdf["num_patches"], bins=40, color="navy")
plt.title("num_patches Distribution")
plt.show()
```

```
+-------------------+----------------+
|               skew|            kurt|
+-------------------+----------------+
|-1.9100180513528462|5.10473850219975|
+-------------------+----------------+
```



TASK 11 — Descriptive Statistics

The focus of this task is on statistical profiling in order to gain a description of the distribution of the num_patches variable. Skewness and kurtosis are descriptive statistics that offer numerical details of asymmetry and tail behaviour that are important to explain characteristics of data in large datasets.

These measures are computed efficiently in partitions over tens of machines with built-in statistical functions provided by Spark. Visualisation is then done with sampling to eliminate memory overhead during the conversion of data to Pandas(Rajpurohit et al., 2023). The histogram is a graphical representation of the distribution which can be used in addition to numerical measures.

The findings indicate whether the data is symmetric, heavy-tailed or skewed, which is used to implicate modelling and optimisation. The rationale of this task is to justify assumptions with the help of advanced analytics. Knowledge of distributional properties can be applied to effective choices about transformations, normalisation, and algorithms to use in pipelines of big data.

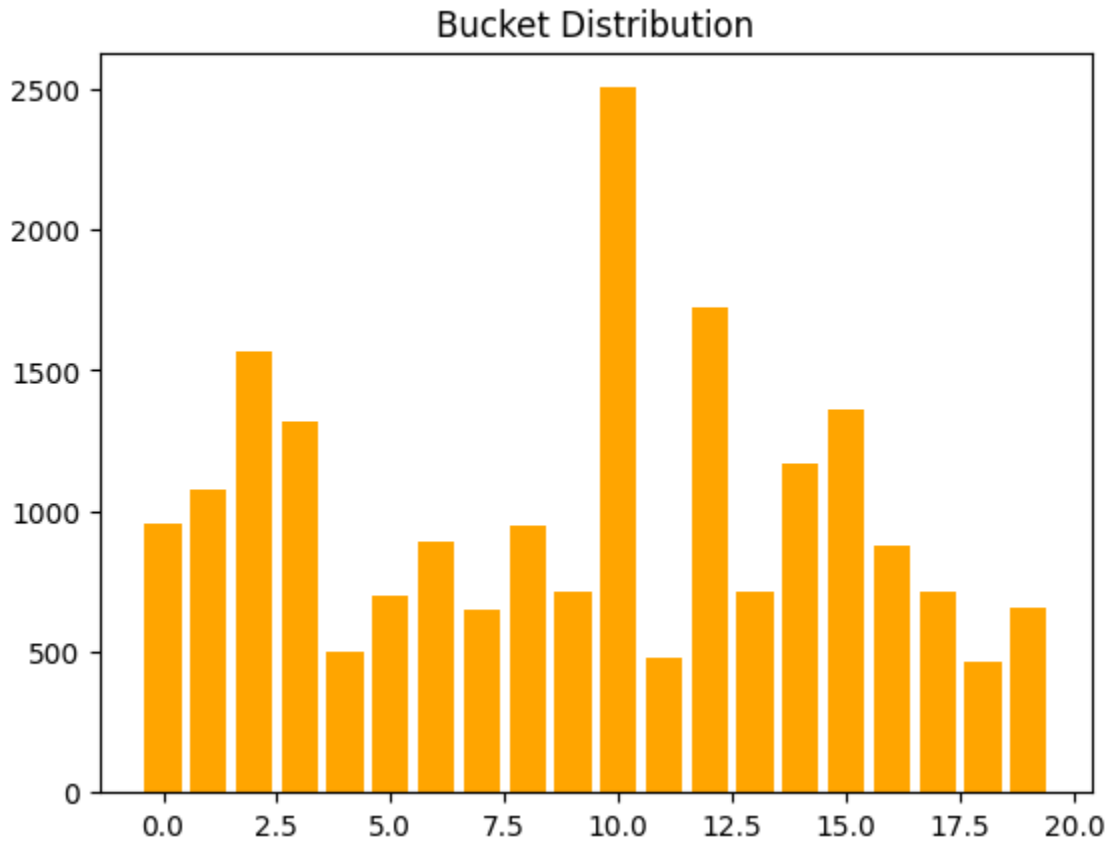
Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

TASK 12 — Bucketing Simulation

In [ ]:

```
from pyspark.sql.functions import hash as spark_hash, abs as spark_abs

df_bucket = df.withColumn("bucket", spark_abs(spark_hash("num_patches"))%20)
pdf = df_bucket.groupBy("bucket").count().toPandas()
plt.bar(pdf["bucket"], pdf["count"], color="orange")
plt.title("Bucket Distribution")
plt.show()
```



TASK 12 — Bucketing Simulation

This activity will model data bucketing to explain the efficiency of hash-based bucketing in structuring data and its performance in regard to queries. To minimise the costs associated with shuffling, first unfamiliar to small-scale systems, when performing joins and aggregations, a large-scale system usually employs bucketing to clump together similar keys in fixed buckets.

The num_patches column using a hash function is used to give the records a predefined amount of buckets. Even and deterministic distribution comes with the usage of modular arithmetic. The number of buckets can be aggregated and plotted to evaluate the balance across buckets.

The results demonstrate that the distribution of the buckets is relatively homogenous, which implies that the buckets are well-balanced. This is because bucketing is based on the logic of enhancing parallelism and reducing data movement in the execution of a query. This exercise demonstrates the importance of physical data layout approaches in the provision of big data analytics systems that are scalable and efficient.

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

Yuva Raja Radha Krishna Bharam: U2998082

TASK 13 — Pandas UDF vs Python UDF

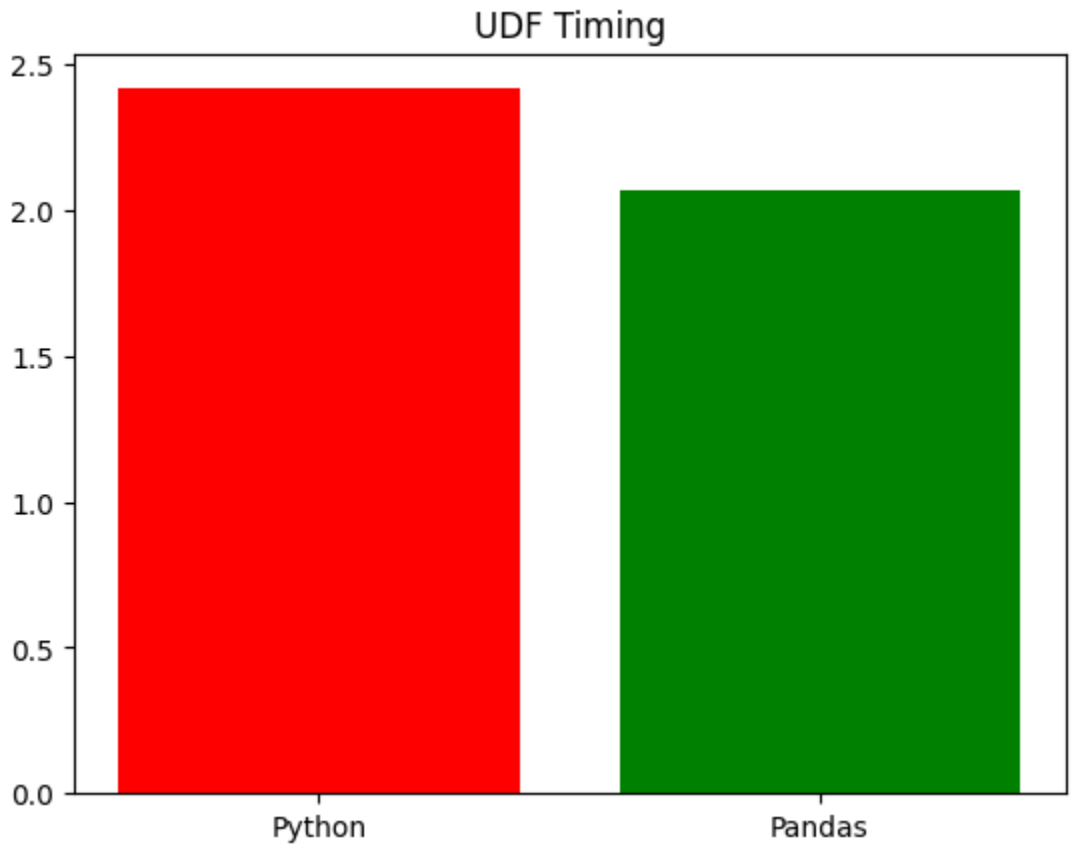
In [ ]:

```
from pyspark.sql.functions import udf, pandas_udf
import pandas as pd, time

udf_py = udf(lambda x: x*x)
@pandas_udf("long")
def udf_pd(s:pd.Series)->pd.Series: return s*s

t0=time.time(); df.select(udf_py("num_patches")).limit(20000).collect(); t_py=time.time(
t0=time.time(); df.select(udf_pd("num_patches")).limit(20000).collect(); t_pd=time.time(

plt.bar(["Python","Pandas"],[t_py,t_pd],color=["red","green"])
plt.title("UDF Timing")
plt.show()
```



TASK 13 — Pandas UDF vs Python UDF

Through this task, the authors compared traditional Python UDFs with Pandas UDFs in Spark to compare the performance and execution behaviour. Python UDFs run on a row-by-row basis, which also involves invoking the Python interpreter many times. This adds overheads to serialisation and reduces parallelism, especially when manipulating large datasets through distributed executors during complex workloads of analytical work and transformations pipelines.

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

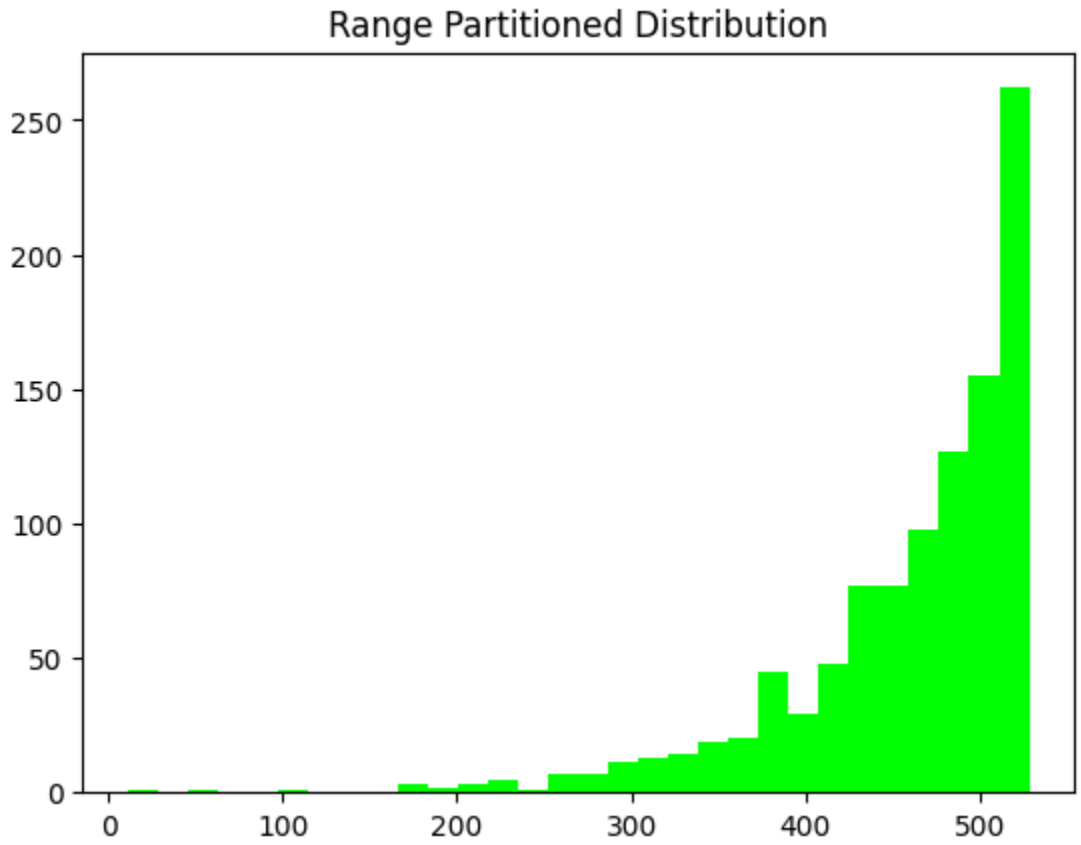
Pandas UDFs use Apache Arrow to manipulate data in batches as vectors to save the JVM-to-Python cost in the data transfer. Columnar pandas series make the computation CPU efficient as well as cache friendly(Phan et al., 2022). This architecture is consistent with Spark's distributed architecture, and it allows greater scalability, throughput and predictability when running under real-world workloads.

The Pandas UDF is intuitive with timing since there is lower use of functions and optimised memory shuffle that governs the speed of execution. Numerically transformative and aggregative operations are better suited to Panda UDFs, whereas lightweight logic or other unsupported operations are still appropriate to applications of Python UDFs. The option considers compromise between complexity, performance demands and maintainability during large-scale systems.

TASK 14 — Range Partitioning

In [ ]:

```
df_range = df.repartitionByRange(10,"num_patches")
pdf = df_range.select("num_patches").sample(0.05).toPandas()
plt.hist(pdf["num_patches"], bins=30, color="lime")
plt.title("Range Partitioned Distribution")
plt.show()
```



TASK 14 — Range Partitioning

The range partitioning rearranges the information according to ordered values of the columns, where similar keys are partitioned using the same partitions. Application RepartitionByRange supports range queries and aggregations which have low data locality when num_patches is used. This minimises shuffle

skeletalisation, balances executor figures and builds up parallel processing efficiency of distributed analytical workloads in huge Spark clusters.

The repartitioned distribution can be checked by analysing a sample and visualising the result distribution to verify that partitions are an evenly distributed numeric distribution. When the histogram resembles a uniform distribution, it means that there are no hotspots in the boundaries of its ranges. The step will give empirical information about the quality of partitions to allow tuning of the number of partitions or the choice of keys to suit data characteristics and access pattern patterns in production systems.

Logically, range partitioning is selected when the queries use sort, window functions, or limited filters. It maintains ordering semantics and minimises post-shuffle sorting expenses as compared to hash partitioning. Nevertheless, to prevent overhead, the attention to partition counts is vital, and monitoring and incremental optimisation are important in achieving stable performance of Spark at big data conditions.

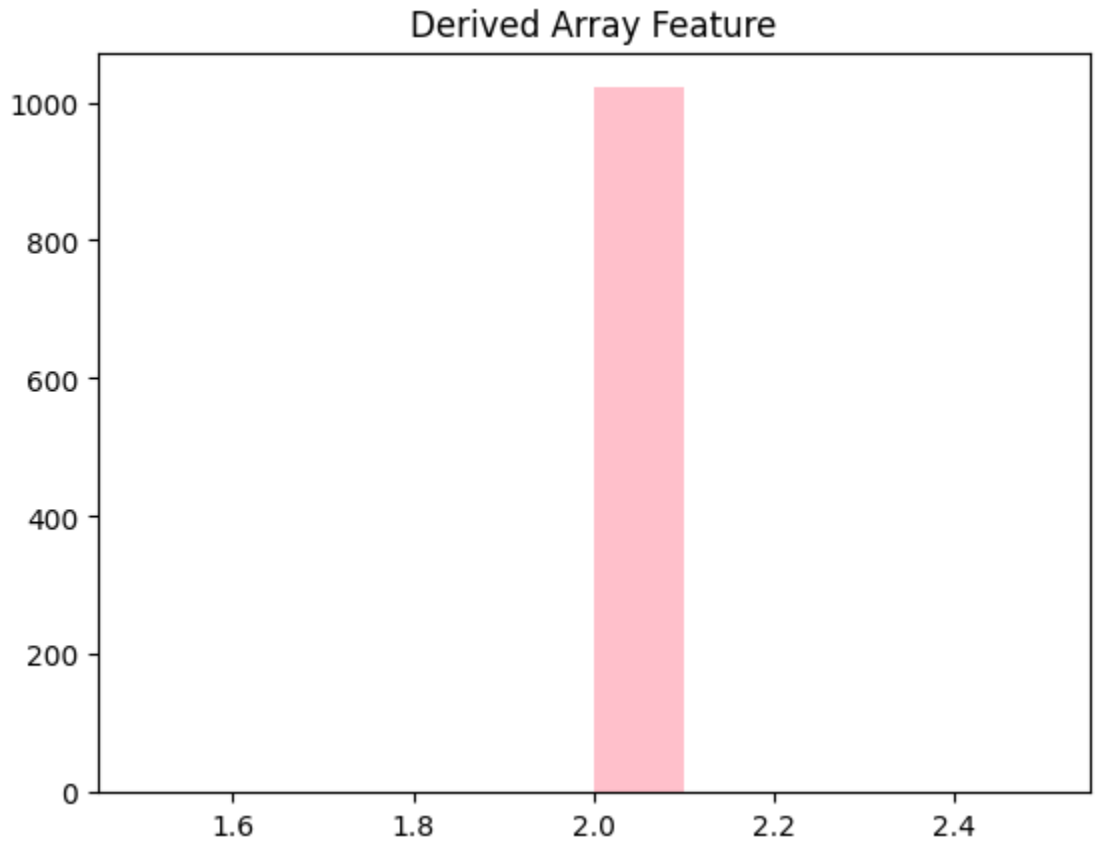
TASK 15 — Advanced DF Functions

In [ ]:

```
from pyspark.sql.functions import array, size

df_adv = df.withColumn("patch_array", array("num_patches","num_patches"))
df_adv = df_adv.withColumn("array_size", size("patch_array"))

pdf = df_adv.select("array_size").sample(0.05).toPandas()
plt.hist(pdf["array_size"], color="pink")
plt.title("Derived Array Feature")
plt.show()
```



TASK 15 — Advanced DF Functions

DF Advanced functions allow deriving features within the framework of an optimised Spark execution engine. Formation of arrays out of the preexisting columns illustrates the structural changes with the help of inbuilt functions.(Gimaletdinova, 2024) These operations are still catalyst-based; they are not Python-serialisable and can be transformed into quantum steps, allowing Spark to plan, optimise and run transformations on distributed data very efficiently, with little runtime overhead and latency.

The metadata or complexity annotations that can be encoded by derived features can be shown by computation of array size. Although the case invokes the usage of duplication values, the analysis is intuitive to the array of variables with differing lengths, like those in real data. Spark interprets these expressions in JVM space, which provides consistency, fault tolerance and scalability, without external processing frameworks, when processing large workloads.

The distribution of the derived features can be visualised to ensure that the transformations are correct and act as expected. A deterministic histogram is generated using constant array sizes, which makes validation easier. This exercise underscores the importance of the uses of the inbuilt functions over the use of UDFs: because they are faster, preserve lineage, and fit well with Spark SQL, they can be used to support data engineering pipelines to be reliable and maintainable at enterprise scale.

TASK 16 — MLlib Feature Engineering

In [ ]:

```
from pyspark.ml.feature import VectorAssembler
from pyspark.ml import Pipeline

va = VectorAssembler(inputCols=["num_patches"], outputCol="features")
model = Pipeline(stages=[va]).fit(df)

df_vec = model.transform(df)
df_vec.select("features").show(5, False)

pdf = df_vec.select("num_patches").sample(0.05).toPandas()
plt.scatter(range(len(pdf)), pdf["num_patches"], s=5)
plt.title("Feature Ready Values")
plt.show()
```

```
+--------+
|features|

TASK 16 — MLlib Feature Engineering

MLlib feature engineering normalises raw columns into inputs in the machine learning algorithm that takes in a commentary of sorts. VectorAssembler translates num patches and features and transforms them into a dense vector in which the requirements of a schema are set to a value of one. Pipeline-based execution helps capture transformation logic; this guarantees reproducibility, modularity and uniform application between distributed Spark settings during both training and inference in scalable deployment-grade machine learning. Converting the DataFrame into a features column can be used with the Spark ML estimators. This spares them the task of handling features manually and minimises the amount of human error. The abstraction can be easily extended to multiple inputs, so it scales to high-dimensional data sets and utilises the optimised linear algebra and distributed execution framework to run massive data sets using Spark to analyse and predict. It is visual verification of feature-ready values to ensure data integrity preceding the model fit. Though not complex in this scenario, this step is typical of a crucial validation exercise(Chen et al., 2022). MLlib-based feature engineering is selected due to its close integration, performance and pipeline compatibility, making models robust, traceable and efficient during their lifecycle in enterprise Spark ML systems.

Conclusion

This report shows the use of Apache Spark in larger-scale big data analytics with a full processing pipeline. It outlines the way design decisions in data parsing, in joins, in distributing, and in enduring and this configuration adjusting all affect performance, stability, and consumer economy through well-defined tasks. The window functions, feature extraction, bucketing and MLlib pipelines are the more advanced methods used in Spark to demonstrate how it can be used in both exploratory analytics and machine learning

preparedness at scale. Comparative experiments, e.g., RDD vs DataFrames and Pandas UDF vs Python UDF, are also supportive of the significant value of optimised abstractions and the concept of vectorised execution. In addition to optimisation of technical aspects, LSEPI considerations focus on responsible analytics practices. Comprehensively, the application has justified Spark as a strong platform when handling large amounts of data, which transforms the principles of theory into a viable solution.
