1. Instruction

The use of social media has changed the whole world of communication and interaction since its rapid development. Although such platforms have created an opportunity for connectivity, they pose a threat to the mental health of users (Feng et al., 2025). Symptoms of depression, anxiety, and loneliness have been attributed to excessive or, rather, maladaptive use. Regardless of the increasing interest, the intricacy of Internet activity and its correlation with mental health outcomes is under-researched.

Learning to associate the activity of social media and psychological well-being is a key to preventive and clinical measures (Sala, et al., 2024). This will be achieved by using advanced data science techniques, where there will be a capability to detect patterns and indications of mental distress that conventional methods fail to capture. The study will be able to advance the body of knowledge, enhance detection, and make contributions to evidence-based suggestions (Hosseini et al., 2023).

The results of this project will have an impact on various stakeholders. The insights may be used by mental health professionals to create better screening tools. These platforms in social media can implement interventions to mitigate the harm, and regulators can enact actions to promote digital well-being (Holly, et al., 2024). In the end, those with anxiety or depression will be able to benefit in terms of their earlier detection and customized interventions.
